

midterm on Friday, can bring usual 1 pg note sheet and calculator. Learning goals through first 5 sections (to Schrod eq and potential energy wells) of learning goals sheet. Not include stuff from today on hydrogen atom-- section #6 of learning goals. Individual plus group again.-- *easier to mark if all perfect*

- 1. Today-- return to models of hydrogen atom Schrodinger model.**
- 2. extension to other atoms & molecules**
- 3. Concept mapping exercise.**

Models of atom

1. Observe atomic spectra, try to develop model for atom to explain.
2. Bohr model-- particular energy levels.
3. How to justify Bohr model energy levels?
4. deBroglie: maybe electron a wave with $\lambda = h/p_{e1}$?
Dav. Germer-- it works.

5. Rethink atom model. Electron acts like a wave, what should be next step in trying to create an electron wave model of hydrogen atom?

a. Come up with an equation that describes the electron wave-- solve to predict shape and properties.

b. Figure out how to get de Broglie standing waves that represent multielectron atoms.

c. Find the boundary conditions on the electron waves

d. Measure energy levels of hydrogen more precisely

a. Schrod. equa.

the 3 D Schrodinger equation

$$-\left[\frac{\hbar^2 \partial^2 \Psi(x, y, z, t)}{2m \partial x^2} + \frac{\hbar^2 \partial^2 \Psi(x, y, z, t)}{2m \partial y^2} + \frac{\hbar^2 \partial^2 \Psi(x, y, z, t)}{2m \partial z^2} \right] +$$
$$- [V(x, y, z)] \Psi(x, y, z, t) = i\hbar \frac{\partial \Psi(x, y, z, t)}{\partial t}$$

What is potential V to use for hydrogen atom?

a. $V(x) = -\frac{ke^2}{x}$

b. $V(x, y, z) = 0$

c. $V(r) = -\frac{ke^2}{r}$

d. $V(r) = +\frac{ke}{r}$

$r = \frac{(x^2 + y^2 + z^2)^{1/2}}{\quad}$ ans. c

Schrodinger eq for Hydrogen, polar coordinates

Define potential energy: $V(r) = -\frac{Zke^2}{r}$

Use S's Eqn
and find solutions:

$$-\frac{\hbar^2}{2\mu} \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial \psi}{\partial r} \right) - \frac{\hbar^2}{2\mu r^2} \left[\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial \psi}{\partial \theta} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2 \psi}{\partial \phi^2} \right] + V(r)\psi = E\psi$$

Reading quiz-- answers graded on correctness, no talking

1. Solutions to Schrodinger eq. for hydrogen atom are characterized by

- a. a single integer, b. 2 integers, c. 3 integers, c. 4 integers
- d. 5 integers ans. 3. n,l,m

2. The energy corresponding to a solution depends on

- a. all three integers n,l,m b. only l and m c. n, l
- d. only l, e. only n.

3. An electron in the 2 p state has

- a. spherically symmetric probability density
- b. significant probability of being at the nucleus
- c. both of the above
- d. neither of the above

Schrodinger eq for Hydrogen, polar coordinates

Define potential energy: $V(r) = -\frac{Zke^2}{r}$

Use S's Eqn

and find solutions:

$$-\frac{\hbar^2}{2\mu} \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial \psi}{\partial r} \right) - \frac{\hbar^2}{2\mu r^2} \left[\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial \psi}{\partial \theta} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2 \psi}{\partial \phi^2} \right] + V(r)\psi = E\psi$$

$$\psi(r, \theta, \phi) = R(r) f(\theta) g(\phi)$$

Apply boundary conditions on ψ in terms of r, θ, ϕ

Messy and tedious but straightforward-- lots of books--
get solution in terms of R, f, g functions.

$$\psi_{nlm}(r, \theta, \phi) = R_{nl}(r) f_{lm}(\theta) g_m(\phi)$$

- a. I remember these from chemistry, but not details.
- b. have never seen before.
- c. I remember these functions, and what the energy and angular momentum of electron in different wave functions depend on.

What do the wave functions look like?

$$\psi_{nlm}(r, \theta, \phi) = R_{nl}(r) f_{lm}(\theta) g_m(\phi)$$

$$R_{nl}(r) = a_0 e^{-r/(na_0)} r^{-1} \mathcal{L}_{nl} \left(\frac{r}{a_0} \right) \quad \text{Laguerre polynomials}$$

$$f_{lm}(\theta) = \frac{(\sin \theta)^{|m|}}{2^l l!} \left[\frac{d}{d(\cos \theta)} \right]^{l+|m|} (\cos^2 \theta - 1)^l$$

$$g_m(\phi) = e^{im\phi}$$

Messy functions!!

**Infinite number of solutions,
labeled by integers, n, l, m**

**Bunch of facts on conditions on n, l, m
and shapes of $\psi_{n,l,m}$ in book.**

$$\psi_{nlm}(r, \theta, \phi) = R_{nl}(r) f_{lm}(\theta) g_m(\phi)$$

Boundary conditions:

Lead to restrictions on wave functions

Lead to quantization in angular momentum and energy

n=2

n=1, 2, 3 ... = Principle Quantum Number

$$E_n = -E_1 / n^2 \quad (\text{for Hydrogen, same as Bohr})$$

2p

l=0, 1, 2, 3 ... = Angular Momentum Quantum Number
= s, p, d, f (restricted to 0, 1, 2 ... n-1)

l=1

$$|\vec{L}| = \sqrt{l(l+1)} \hbar$$

m=-1, 0, 1

m = ... -1, 0, 1.. = z-component of Angular Momentum
(restricted to -l to l)

$$L_z = m\hbar$$

Energy Diagram for Hydrogen

Energy only depends on n
 (NOT true for hydrogen if look more
 carefully-- improved solution,
 including magnetic effects--
 important triumph of Sch. Eq.).
Completely wrong for multi-
 electron atoms.

An electron in the Hydrogen atom is excited to the following electronic state:

$$\psi_{n=3,l=1,m=0}(r, \theta, \phi) = R_{31}(r) f_{10}(\theta) g_0(\phi)$$

with energy $E_{n=3} = -E_1 / (n = 3)^2$.

How many electronic energy levels have the same energy as this one?

- (a) 1
- (b) 2
- (c) 3
- (d) 5
- (e) 9

Comparing H atom & Infinite Square Well:

Infinite Square Well: (1D)

- $V(x) = 0$ if $0 < x < L$
 ∞ otherwise

- Energy eigenstates:

$$E_n = \frac{n^2 \pi^2 \hbar^2}{2mL^2}$$

- Wave functions:

$$\psi_n(x) = \sqrt{\frac{2}{L}} \sin\left(\frac{n\pi x}{L}\right)$$

$$\Psi_n(x, t) = \psi_n(x) e^{-iE_n t / \hbar}$$

H Atom: (3D)

- $V(r) = -Zke^2/r$

- Energy eigenstates:

$$E_n = -\frac{mZ^2 k^2 e^4}{2\hbar^2 n^2}$$

- Wave functions:

$$\Psi_{nlm}(r, \theta, \phi) = R_{nl}(r) f_{lm}(\theta) g_m(\phi)$$

$$\Psi_{nlm}(r, \theta, \phi, t) = \Psi_{nlm}(r, \theta, \phi) e^{-iE_n t / \hbar}$$

Schrodinger finds quantization of energy and angular momentum:

$$n=1, 2, 3 \dots \quad l=0, 1, 2, 3 \text{ (restricted to } 0, 1, 2 \dots n-1)$$
$$E_n = -E_1 / n^2 \quad |\vec{L}| = \sqrt{l(l+1)} \hbar$$

How does Schrodinger compare to what Bohr thought?

- I. The energy of the ground state solution is _____
 - II. The angular momentum of the ground state solution is _____
 - III. The location of the electron is _____
- a. same, same, same
 - b. same, same, different
 - c. same, different, different
 - d. different, same, different
 - e. different, different, different

Schrodinger finds quantization of energy and angular momentum:

$$n=1, 2, 3 \dots \quad l=0, 1, 2, 3 \text{ (restricted to } 0, 1, 2 \dots n-1)$$
$$E_n = -E_1 / n^2 \quad |\vec{L}| = \sqrt{l(l+1)} \hbar$$

How does Schrodinger compare to what Bohr thought?

I. The energy of the ground state solution is same

same: $E_n = -E_1 / n^2$ for both ($E_1 = -13.6\text{eV}$)

II. The angular momentum of the ground state solution is different

Schrodinger:

Ground state

($n, l, m = 1, 0, 0$) so $L=0$

Bohr and deBroglie said:

$L = n\hbar$, so $L = \hbar$ in ground state.

(Bohr and deBroglie were wrong)

III. The location of the electron is different

Schrodinger:

spread out as spherical
cloud around nucleus

Bohr said: orbiting as point

particle at fixed radius (Both wrong)

deBroglie said: spread out as

wave, but confined to fixed radius

Schrodinger's solution does everything that Bohr's could not!

Here are 3 different electronic state in the hydrogen atom

$$\psi^1_{n=5,l=4,m=4}(r, \theta, \phi) = R_{5,4}(r) f_{4,4}(\theta) g_4(\phi)$$

$$\psi^2_{n=45,l=44,m=44}(r, \theta, \phi) = R_{45,44}(r) f_{44,44}(\theta) g_{44}(\phi)$$

$$\psi^3_{n=1,l=0,m=0}(r, \theta, \phi) = R_{1,0}(r) f_{1,0}(\theta) g_0(\phi)$$

(orbital angular momentum $|\vec{L}| = \sqrt{l(l+1)} \hbar$).

If you could look at the probability density Vs time for the 3 wavefunctions above, which ones would move around in space the most rapidly?

Rank the 3 wavefunctions (1,2, and 3) from slowest to fastest motion:

- (a) 1 slowest then,2,3 (b) 3,1,2 (c) 3,2,1
(d) 2,3,1 (e) All three are the same

e) all the same-- not changing!

When in single energy eigenstate, which all these states are, no time dependence in probability distribution. See sim.

Remember last Friday, only mixtures of different energy eigenstates give interference term that gives time dependence.

So have angular velocity-- going around the nucleus, but probability distribution does not change.

Angular momentum is represented by phase in the angular wave function, just like kinetic energy, by spatial variation in wave function.

PLUS Schrodinger's also works for multi-electron atoms

Easy to describe, hard to solve. What's different for these cases?
Potential energy (V) changes! More protons AND other electrons)

$$V \text{ (for } q_1) = kq_{\text{nucleus}}q_1/r_1 + kq_2q_1/r_{2-1} + kq_3q_1/r_{3-1} + \dots \\ +V(\text{for } q_2) +V(q_3), \dots$$

Need to account for all the interactions among the electrons
Must solve for all electrons at once! ($\psi_1, \psi_2, \psi_3, \psi_4, \dots$)

Clever approximations and big computer programs!

Solutions change: **different shaped wave functions**

higher $Z \rightarrow$ more protons \rightarrow electrons in 1s more strongly bound \rightarrow radial distribution quite different

general shape (p-orbital, s-orbital) **similar but not same!**

- energy of wave functions affected by Z (# of protons)

higher $Z \rightarrow$ more strongly bound (more negative total energy)

Molecules-- same physics and equa. but even messier to solve¹⁸

with work, Schrodinger eq. makes sense of periodic table

Labels for Carbon (C):
 6 — Atomic number
 C — Symbol
 12.01 — Atomic weight

(c)1998
Kremer Paul

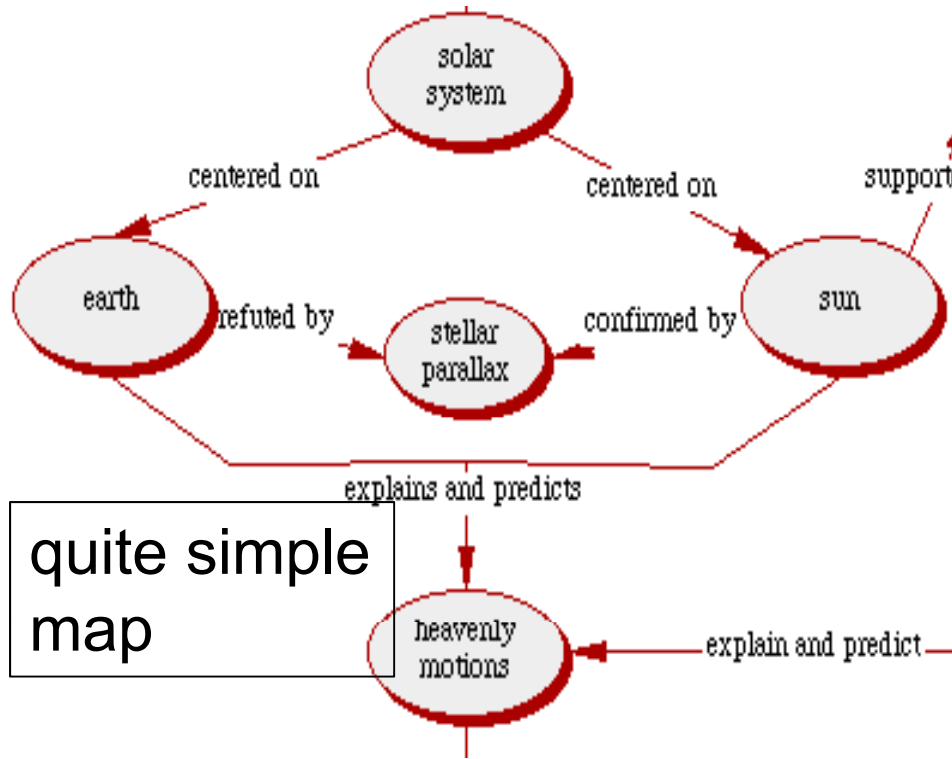

models of hydrogen (and other atoms)

1. Thompson- plum pudding
2. Rutherford solar system
3. Bohr
4. de Broglie standing waves
5. Schrodinger--

6. Schrodinger with electron spin added
good for almost everything that matters, to ~ 6 digits
used for all normal day to day physics

7. Dirac -- spin and relativity, negative energy states
8. Quantum electrodynamics (quantum field theory)
9. Electroweak unification

10. Grand unification???

Concept map-- way to think about what are the most important ideas and concepts, and how they fit together. Experts do all the time. Good for pulling together all the stuff we covered and getting it organized in your mind.

Brainstorm for ~5 minutes-- list of important idea (“brainstorm”, just throw out ideas, don’t waste time arguing, do that later.) Then decide which belong on list, lay out on map with links. Then mark the 6 ovals that are THE 6 MOST IMPORTANT ideas. Sketch out practice map on small paper. Then do final one on large paper with group number. 12:00 post. Everyone has to rank the maps of at least 4 other groups, with brief reasons why ranking, turn in ranking sheets. 3 points for ranking sheet.

Physics vs Chemistry view of orbits:

2p wave functions
(Physics view)
($n=2, l=1$)

Dumbbell Orbits
(chemistry)

p_x = superposition

(addition of $m=-1$ and $m=+1$)

p_y = superposition

(subtraction of $m=-1$ and $m=+1$)
